

What is GIT?

VCS stands for Version Control System.

Since we have been talking about Git, Git is just one specific (and very famous) brand of a VCS. A Version Control System is the broader category of software designed to track and manage changes to code or files over time. If you have ever used "Version History" in Google Docs or "Track Changes" in Microsoft Word, you have used a basic form of version control. A true VCS just scales that concept up for massive software projects.

Here is why developers rely on them:

Complete History: A VCS records who made a change, what exactly was changed, and when it happened.

The "Undo" Button: If a new update breaks an app, a VCS allows the team to instantly roll back to the version from yesterday that worked perfectly.

Teamwork: It acts like a traffic cop, allowing multiple developers to work on the exact same project simultaneously without overwriting each other's work.

Command	What it does	Example
<code>git config</code>	Sets your author name and email to be attached to your saves.	<code>git config --global user.name "Your Name"</code>
<code>git init</code>	Starts a brand new Git repository in your current folder.	<code>git init</code>
<code>git clone</code>	Downloads a project from the internet onto your computer.	<code>git clone https://github.com/repo.git</code>
